Purpose

Time series is one of the most important types of data. It can be produced from Sensors, RFIDS, financial analysis, ...

Such massive data imply vast amount of privacy

We want to anonymize data preserving complex query such as range and pattern matching queries.

So... use k-anonymity? No, it suffer from Pattern Loss

Then... (k, P)-anonymity!

k and P Anonymization Levels

k-requirement: Each anonymization envelope appears at least k times.

P-requirement: Consider any k-group G of time series having the identical anonymization envelope, for any time series (r) in G, there are at least P-1 other time series in G having the same QI pattern representation as PR[r]

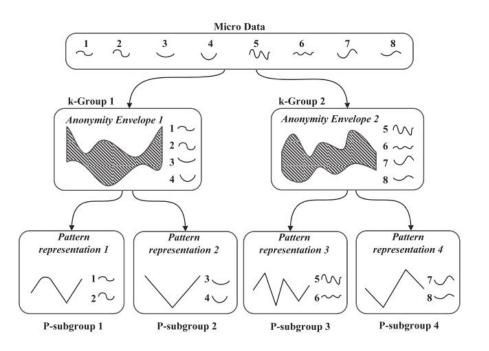

Why two levels?

First level: k-anonymity is required for time series in the entire database. That means the records in the published database can be grouped by the quasi-identifier attribute values, and each group should contain at least k records.

Second level: P-anonymity is required for the pattern representations (PRs) associated with each record in a same group. Specifically, each group can be divided into subgroups, each of which contains at least P records having identical PRs.

Main purpose is to achieve minimal pattern loss

Why two levels?

The k-groups and P-subgroups of (k,P)-Anonymity

Supporting Pattern-Preserving Anonymization for Time-Series Data

Lidan Shou, Xuan Shang, Ke Chen, Gang Chen, and Chao Zhang

Abstract—Time series is an important form of data available in numerous applications and often contains vast amount of personal privacy. The need to protect privacy in time-series data white effectively supporting complex quaries on them pose monthful childrages to the database community. We study the amorphication of time series white trying to support complex quories, such as range and pattern matching queries, on the published data. The conventional k-anonymity model cannot effectively address this series. This model publishes both the attribute values and the patterns of time series in separate data forms. We demonstrate that or node) can prevent linkage attacks on the published data while effectively support a wide variety of gueries on the anonymized data We propose two algorithms to erforce (s, IP)-ancorprity on time-series data. Our ancorprity mode supports outcomized data publishing, which allows a cortain port of the values but a different part of the pattern of the ancorpritized time series to be published simulationary. We ensert estimation techniques to support such recognition on such customized data.

1 INTRODUCTION

human society. In recent years, the popularity of sensor networks, RFIDs, and wireless positioning equipments has further driven the production of time-series data to unprecedented volume and complexity. The publicity of these data on the Internet has nurtured the most creative applications ranging from financial analysis to seein and section of the desired community tracking and partner matching. However, such the season death and on imply vast amount of privacy, which is the disclosed. However, the time-moster data too imply vast amount of privacy, which is the disclosed. However, the time-moster database values and their patterns can be used as

ammenting interest, many features design and a substrate arthrest values and their patterns can be used as success for abuses and crimes.

In a success for abuses and crimes.

Thereby protects in many become explained as a success for abuses and crimes.

The property of the control of the crime is a substrate and the vary that they are used in particular, the opportunit of the quality and "complete" question and for each the size that they are used in particular, the opportunit of the quality and "complete" question and for each to the control of the crime and the crime

Executions

Dataset 1

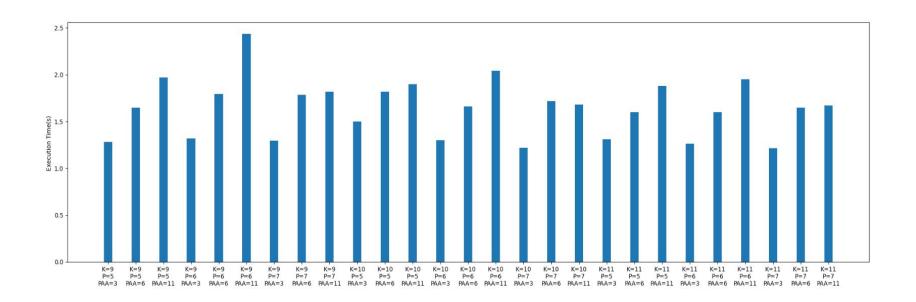

StackOverflow Questions Count Time Series: consist of count of various questions of specific libraries for each month.

Used for time analysis and Instant Value Loss analysis.

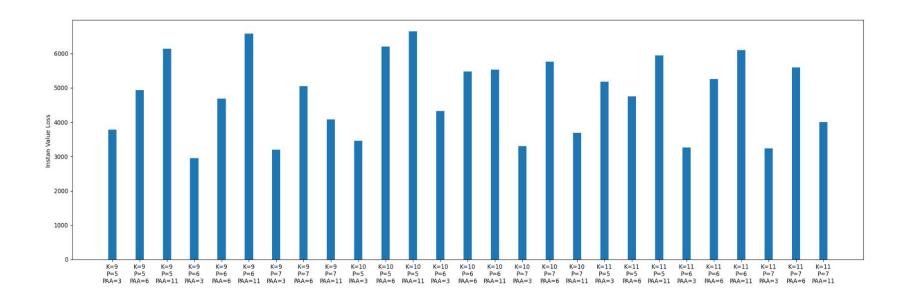

MLTollsStackOverflow:

- 82 columns
- 133 rows

Analysis (1) - Execution Time

Analysis (1) - Instant Value Loss

Results of Analysis (1)

Best solutions:

- Execution Time: K=11, P=7, PAA=3
- Instant Value Loss: K=9, P=6, PAA=3

The best case is about halfway between the two metrics and looking carefully at the two graphs and comparing them we can see that in this case:

There is the best compromise for this test run.

Dataset 2

Nifty 50 Index Minute data (2015 to 2022): The dataset contains OHLC (Open, High, Low, and Close) prices of daily data from Jan 2015 to Jan 2022.

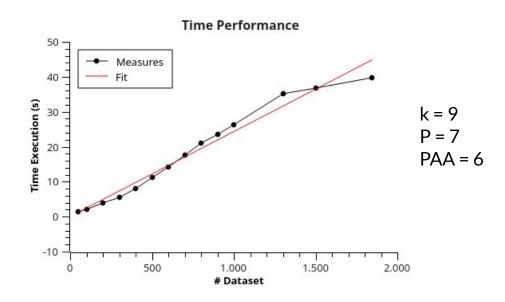

Used for time analyses and Instant Value Loss analysis.

NIFTY50-1_day_with_indicators:

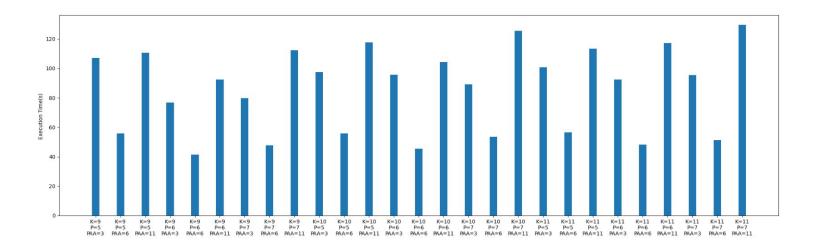

- 60 columns
- 1845 rows

https://www.kaggle.com/datasets/debashis74017/nifty-50-minute-data

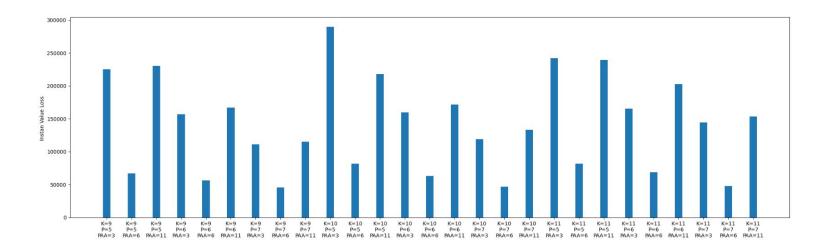

Analysis (2) - Time Performance

Analysis (2) - Execution Time

Analysis (2) - Instant Value Loss

Results of Analysis (2)

Best solutions:

- Execution Time: K=9, P=6, PAA=6
- Instant Value Loss: K=9, P=7, PAA=6

The best case still remains one of these two since over several runs these are the values that appear several times as the best solutions.

Statistically these parameters can give a best case for one of the two metrics or both.

Limits in parameter tuning

It can be seen that (k,P)-anonymity is actually a generalization of k-anonymity.

- If P = 1 and remove all PRs from the dataset:
 Results will be same as conventional k-anonymity based
- If P == k:

Results will be an enhanced version of conventional k-anonymity based on pattern similarity

In general, P must be no greater than k
